Introduction to classification problems

The response variable Y is qualitative, taking values in an unordered set C . Depending on the cardinality of C ,

- binary classification: $|C| = 2$
 - ▶ email is $C = \{\text{spam}, \text{non-spam}\}$
 - ▶ the status of patient is $C = \{\text{cancer}, \text{non-cancer}\}$
- Multi-class classification: $|C| > 2$
 - ▶ digit is $C = \{0, 1, \dots, 9\}$
 - ▶ eye color is $C = \{\text{brown}, \text{blue}, \text{green}\}$.

Given the training data: $\mathcal{D}^{train} = \{(x_1, y_1), \dots, (x_n, y_n)\}$, with $y_i \in C$ and $x_i \in \mathbb{R}^p$, our goals are to:

- Build a classifier (a.k.a. a rule)

$$\hat{f} : \mathbb{R}^p \rightarrow C$$

that assigns a future observation $x \in \mathbb{R}^p$ to a class label $\hat{f}(x) \in C$.

- Assess the accuracy of this classifier \hat{f} (classification accuracy).
- Understand the roles of different features in \hat{f} (estimation and interpretability).

The metric used in classification

Let (X, Y) be a random pair, independent of \mathcal{D}^{train} . Let us encode the labels as

$$C = \{0, 1, 2, \dots, K - 1\}.$$

For any classifier \hat{f} , we evaluate it based on the **expected error rate**

$$\mathbb{E}\left[1\{Y \neq \hat{f}(X)\}\right].$$

Question: what is the best classifier?

The Bayes rule and the Bayes error

The Bayes classifier (rule) is a function: $f^* : \mathbb{R}^P \rightarrow C$, that minimizes the expected error rate as

$$f^*(x) = \operatorname{argmin}_{\hat{f}(x) \in C} \mathbb{E} \left[1\{Y \neq \hat{f}(X)\} \mid X = x \right], \quad \forall x \in \mathbb{R}^P.$$

Correspondingly, its expected error rate

$$\mathbb{E} \left[1\{Y \neq f^*(X)\} \right]$$

is called the **Bayes error rate** which is the smallest.

Draw analogy in the regression context

In regression context

$$Y = f^*(X) + \epsilon,$$

the regression function is the best predictor: for any $x \in \mathbb{R}^p$,

$$\begin{aligned} f^*(x) &= \mathbb{E}[Y \mid X = x] \\ &= \operatorname{argmin}_{\hat{f}(x)} \mathbb{E}[(Y - \hat{f}(X))^2 \mid X = x] \end{aligned}$$

Its MSE is the smallest (a.k.a. irreducible error)

$$\mathbb{E}[(Y - f^*(X))^2] = \operatorname{Var}(\epsilon) = \sigma^2.$$

The Bayes rule

For any $x \in \mathbb{R}^p$,

$$\begin{aligned} f^*(x) &= \operatorname{argmin}_{\hat{f}(x) \in C} \mathbb{E} \left[1\{Y \neq \hat{f}(X)\} \mid X = x \right] \\ &= \operatorname{argmin}_{\hat{f}(x) \in C} \mathbb{P} \{ Y \neq \hat{f}(x) \mid X = x \}. \end{aligned}$$

Intuitively, $f^*(x)$ assigns each x to its most probable class, that is,

$$f^*(x) = \operatorname{argmax}_{k \in C} \mathbb{P} \{ Y = k \mid X = x \}.$$

The Bayes classifier, f^* , is our target to estimate / learn in classification problems.

The Bayes Error Rate

The Bayes error rate at $X = x$ is

$$\begin{aligned}\mathbb{E}[1\{Y \neq f^*(X)\} \mid X = x] &= \mathbb{P}\{Y \neq f^*(X) \mid X = x\} \\ &= 1 - \mathbb{P}\{Y = f^*(X) \mid X = x\} \\ &= 1 - \max_{1 \leq j \leq K} \mathbb{P}\{Y = j \mid X = x\}.\end{aligned}$$

The Bayes error rate is:

- between 0 and 1.
- typically > 0 .

Binary classification

In binary classification, $C = \{0, 1\}$ and the Bayes classifier is

$$f^*(x) = \begin{cases} 1, & \text{if } \mathbb{P}\{Y = 1 \mid X = x\} \geq 0.5; \\ 0, & \text{otherwise.} \end{cases}$$

Learning the Bayes classifier equals to estimating [the conditional probability](#)

$$p(x) := \mathbb{P}\{Y = 1 \mid X = x\}, \quad \forall x \in \mathbb{R}^p,$$

a function: $\mathbb{R}^p \rightarrow \{0, 1\}$.

Why Not Regression?

- In the binary case, $Y \in \{0, 1\}$,

$$p(X) = \mathbb{P}\{Y = 1 \mid X\} = \mathbb{E}[Y \mid X].$$

Recall the regression setting,

$$Y = f(X) + \epsilon = \mathbb{E}[Y \mid X] + \epsilon.$$

- Can we use the regression approach (such as OLS) to estimate $\mathbb{E}[Y \mid X]$?

Using OLS to predict $p(X) = \mathbb{P}(Y = 1 \mid X)$

- Yes, we could (as commonly done in practice).
- However, OLS predict $p(X)$ by

$$\hat{\beta}_0 + \hat{\beta}_1 X_1 + \cdots + \hat{\beta}_p X_p,$$

which could be less than zero or bigger than one.

- A more tailored approach is needed!

Linear Regression versus Logistic Regression in binary classification

- Left: Estimated probability of default using linear regression. Some estimated probabilities are negative! The orange points represent the 0/1 values coded for default (No or Yes).
- Right: Predicted probabilities of default using logistic regression. All probabilities lie between 0 and 1.

Classification approaches

How to estimate

$$p(x) = \mathbb{P}\{Y = 1 \mid X = x\}$$

for any $x \in \mathbb{R}^p$?

The same categories as regression:

- Parametric methods
 - ▶ Logistic regression
 - ▶ Discriminant analysis
- Non-parametric methods
 - ▶ Support vector machine
 - ▶ k -nn
 - ▶ Classification tree

How to select among a set of classifiers?

For a given classifier $\hat{f} : \mathbb{R}^p \rightarrow C$, we have

- **Training 0-1 error rate.**

$$\frac{1}{n} \sum_{i=1}^n 1\{y_i \neq \hat{f}(x_i)\}$$

- **Test 0-1 error rate** when we have the test data $\{(x_{T_1}, y_{T_1}), \dots, (x_{T_m}, y_{T_m})\}$,

$$\frac{1}{m} \sum_{i=1}^m 1\{y_{T_i} \neq \hat{f}(x_{T_i})\}.$$

- **Cross-validation based on 0-1 error rate** when we don't have the test data:
- More metrics on binary classification.
